Abstract. Computing with data values that are some kind of trees — finite, infinite, rational— is at the core of declarative programming, either logic, functional or functional-logic. Understanding the logic of trees is therefore a fundamental question with impact in different aspects, like language design, including constraint systems or constructive negation, or obtaining methods for verifying and reasoning about programs. The theory of true equality over finite or infinite trees is quite well known. In particular, a seminal paper by Maher proved its decidability and gave a complete axiomatization of the theory. However, the sensible notion of equality for functional and functional-logic languages with a lazy evaluation regime is strict equality, a computable approximation to true equality for possibly infinite and partial trees. In this paper, we investigate the first-order theory of strict equality, arriving to remarkable and not obvious results: the theory is again decidable and admits a complete axiomatization, not requiring predicate symbols other than strict equality itself. Besides, the results stem from an effective —taking into account the intrinsic complexity of the problem— decision procedure that can be seen as a constraint solver for general strict equality constraints.

1 Introduction

Computing with data values that are —or can be interpreted as— some kind of trees is at the core of declarative programming, either logic, functional or functional-logic programming. The family of trees may vary from finite trees, for the case of standard logic programming, infinite rational trees, for the case of Prolog-II and variants, or infinite trees (that correspond to data values in constructor data-types) for the case of functional or functional-logic programming that allow non-terminating programs by following a lazy evaluation regime.

Understanding trees, in particular the logical principles governing tree equality, is a fundamental question with impact in different aspects of declarative

programming languages. For instance, adding constructive negation abilities to a logic language requires solving complex Herbrand constraints over finite trees.

The theory of true equality $\approx$ over finite or infinite trees is quite well known. In a seminal paper [10], Maher proved its decidability and gave a complete axiomatization for the cases of finite and infinite trees, and finite and infinite signatures. In another influential paper [5], the authors provided more effective decision procedures, based on reduction to solved forms by quantifier elimination.

However, true equality is not the sensible notion to consider in lazy functional or functional-logic languages like Haskell, Curry or Toy [11, 7, 3]. In those, the possibility of non-terminating programs handled with lazy evaluation implies that denotations of expressions may be seen as infinite trees. Furthermore, trees may be partial, in the sense that some of their components may be undefined. For instance, with the definitions $\text{loop} = \text{loop}$ and $l = [\text{loop}]$, $l$ can be seen as computing the infinite partial list $[\bot, \bot, \bot, \ldots]$. However, true equality over partial trees is not Scott continuous (hence not computable). It is then replaced by strict equality $==$ — the largest continuous approximation to $\approx$ —, defined as the restriction of $\approx$ to finite and total trees. The theories of equality and of strict equality are far from being the same, starting by the fact that $==$ is not even reflexive.

As far as we know, a comprehensive study of the full first-order theory of strict equality has not been done before. Certainly, strict equality is incorporated as primitive in the aforementioned languages, and there are several works incorporating various Herbrand constraint systems — and corresponding solving procedures — to functional logic languages [1, 8, 2]. But in all cases, the considered class of formulae over $==$ is only a subset of general first-order formulae.

The aim of this paper is precisely to investigate the full first-order theory of strict equality over the algebra $\mathcal{IT}$ of possibly infinite partial trees. Note that decidability and existence of complete axiomatization for $\approx$ says nothing about the same problems for strict equality, even if $==$ is a strict subset of $\approx$ (i.e., $\forall x \cdot y \ ( x == y \to x \approx y )$ is valid in $\mathcal{IT}$). These are indeed the main questions tackled in this paper:

- Does the theory of strict equality over $\mathcal{IT}$ admit a complete recursive axiomatization?
- In the affirmative case, is it possible that the axioms use only the symbol $==$? We cannot discard a priori the possibility that the axiomatization needs an explicit connection of $==$ to $\approx$. That would result in a more complicated set of axioms and transformation rules, since to the axioms for $\approx$ of [10] we would need to add new axioms establishing the connection to $==$, like the formula stated above.
- A complete recursive axiomatization of a theory implies its decidability (at least a brute force decision procedure exists). Can we give a more practical decision procedure, in the style of [5]? As a matter of fact, such a procedure — if existing — will be itself a proof of completeness for the theory.

1 By true equality we mean $t_1 \approx t_2$ iff $t_1$ and $t_2$ are the same tree.
We obtain affirmative answers to these questions, both in the cases of infinite and finite signatures. Our paper does not look for immediate applications, keeping in a theoretical realm and trying to achieve fundamental and not obvious results about strict equality that could be a basis for potential applications: the design of constraint systems more expressive than existing ones or the development of reasoning frameworks for functional-logic programs with built-in equality.

The organization of the paper is as follows: in the next section, we provide preliminary definitions and notation. In Section 3, we give an axiomatization for strict equality. Next, in Section 4, we introduce the transformation rules that will be used in the decision methods of Section 5, distinguishing the cases of infinite and finite signatures. Finally, in Section 6, we discuss complexity issues and future work. The appendix contains some pending proofs and auxiliary results.

2 Preliminaries

Let $V$ be a set of countable variables and $\Sigma = \mathcal{P}_\Sigma \cup \mathcal{F}_\Sigma$ a signature of predicate and function symbols where each symbol $s$ has an associated arity $n$, denoted by $s/n$, and $\mathcal{P}_\Sigma$ exclusively consists of the symbol $==/2$, known as strict equality. For technical convenience, we assume that $\mathcal{F}_\Sigma$ contains at least a 0-ary function symbol (constant), an $n$-ary function symbol with $n > 0$ and a distinguished 0-ary function symbol $\bot$ known as bottom. If $\Sigma$ contains a finite number of function symbols, then $\Sigma$ is said to be finite. Otherwise, $\Sigma$ is infinite. By using the name function, we follow the tradition of first-order logic, but note that the notion of function corresponds to the notion of free constructor in functional/functional-logic programming and not to defined function, which plays no role in this paper.

We consider the classical definitions of finite and infinite ground trees. The interested reader is referred to [4] for an exhaustive definition. A tree is said to be partial if it contains $\bot$ at some node. Otherwise, the tree is total. The algebra of finite and infinite trees are respectively denoted by $\mathcal{FT}$ and $\mathcal{IT}$. Besides, we also refer to [5] for the definitions that do not appear in this paper.

A term (or constructor term) is either a variable $v \in V$ or an expression $f(t_1,\ldots,t_n)$ where $f/n \in \mathcal{F}_\Sigma$ and $t_1,\ldots,t_n$ are terms. For any terms $t$ and $s$, the expression $t[s]$ denotes that $s$ occurs in $t$ (that is, $s$ is a subterm of $t$). For any $n > 0$, a $n$-tuple of terms is denoted by $(t_1,\ldots,t_n)$ and abbreviated by $t$. When convenient, we also treat $t$ as the set of its components. As for the case of trees, a term $t$ is said to be partial if $t = s[\bot]$, and $t$ is total otherwise. We denote by $\text{Var}(t)$ the set of variables occurring in $t$. Besides, a term is said to be ground iff it is variable-free. The size of a term $t$ is the number of function symbols occurring in $t$.

A sentence $\phi$ is an arbitrary first-order formula built with $\Sigma$. In our case, the only predicate symbol is $==$. Thus atomic formulas are true, false, strict equations $t_1 == t_2$ or negated equations $\neg t_1 == t_2$. Being $\mathcal{r} = (r_1,\ldots,r_n)$ and $\mathcal{s} = (s_1,\ldots,s_n)$, $\mathcal{r} == \mathcal{s}$ abbreviates $r_1 == s_1 \land \ldots \land r_n == s_n$ and $\neg \mathcal{r} == \mathcal{s}$ abbreviates the disjunction of negated equations $\neg r_1 == s_1 \lor \ldots \lor \neg r_n == s_n$. Sentences may use propositional connectives ($\neg$, $\land$, $\lor$, $\rightarrow$, $\leftrightarrow$) and quantifiers.
The symbol $Q$ stands for both kinds of quantifiers. The set $\text{Free}(\phi)$ of free variables of $\phi$ is defined as usual. If $\text{Free}(\phi) = \emptyset$, $\phi$ is closed. $\phi^Q$ denotes the $Q$-closure of $\phi$, and $\phi^{Q,\forall}$ denotes the sentence $Q\forall \phi$, where $\overline{\pi} = \text{Free}(\phi) \setminus \overline{w}$.

Now we recall some semantics of first order logic. An interpretation $\mathcal{A}$ is a carrier set $A$ together with interpretations $f^M, p^M$ for the symbols in $\Sigma$. Given $\mathcal{A}$, an assignment $\sigma$ maps variables to values in $A$; if $\phi \sigma$ is true (according to standard rules for truth-valuation) in $\mathcal{A}$, we say that $\sigma$ is a solution (in $\mathcal{A}$) of $\phi$. $\mathcal{A}$ models $\phi$, written $\mathcal{A} \models \phi$, if all assignments are solutions in $\mathcal{A}$ of $\phi$. Notice that, for given $\mathcal{A}, \phi$ and $\sigma, \sigma$ must be a solution in $\mathcal{A}$ either of $\phi$ or of $\neg \phi$; moreover, if $\phi$ is closed, either $\mathcal{A} \models \phi$ or $\mathcal{A} \models \neg \phi (\leftrightarrow \mathcal{A} \not\models \phi)$.

A theory $\mathcal{T}$ is a set of closed sentences. $\mathcal{A}$ is a model of $\mathcal{T}$, written $\mathcal{A} \models \mathcal{T}$, if $\mathcal{A} \models \phi$ for each $\phi \in \mathcal{T}$. A formula $\phi$ is a logical consequence of $\mathcal{T}$, written $\mathcal{T} \models \phi$, if $\mathcal{A} \models \phi$ whenever $\mathcal{A} \models \mathcal{T}$. This notation extends naturally to sets $\Phi$ of formulas. A sentence $\phi$ is satisfiable (or solvable) in $\mathcal{T}$, if $\mathcal{T} \models \phi^3$. A theory $\mathcal{T}$ is complete iff for any closed sentence $\phi$ either $\mathcal{T} \models \phi$ or $\mathcal{T} \models \neg \phi$ holds. The theory $\mathcal{T}_A$ of $\mathcal{A}$ is the set of all closed $\phi$ such that $\mathcal{A} \models \phi$. Note that $\mathcal{T}_A$ is always complete. A complete axiomatization of $\mathcal{A}$ is a theory $\mathcal{S} \subseteq \mathcal{T}_A$ such that $\mathcal{S} \models \mathcal{T}_A$ (or, equivalently, $\mathcal{S}$ is a complete theory and $\mathcal{A} \models \mathcal{S}$). Usually one is interested in recursive axiomatizations where the property '$\phi \in \mathcal{S}$' is decidable.

Given two sentences $\phi_1$ and $\phi_2$, a transformation rule $\phi_1 \mapsto \phi_2$ replaces any occurrence of $\phi_1$ in a formula (module variable renaming) with $\phi_2$. The application of a transformation rule $R$ to $\phi_1$ yielding $\phi_2$ is denoted by $\phi_1 \overset{R}{\mapsto} \phi_2$. A transformation rule $R$ is said to be correct in a theory $\mathcal{T}$ iff for any two formulas $\phi_1$ and $\phi_2$ such that $\phi_1 \overset{R}{\mapsto} \phi_2$ we have that $\phi_1$ and $\phi_2$ are logically equivalent in $\mathcal{T}$, i.e., $\mathcal{T} \models \phi_1 \leftrightarrow \phi_2$.

3 An Axiomatization of Strict Equality

Strict equality is a particular case of classical equality where, besides being syntactically equal, two terms have to be finite and total to be strictly equal.

**Definition 1 (Strict equality).** Two trees $t_1$ and $t_2$ are strictly equal, denoted by $t_1 == t_2$, iff $t_1$ and $t_2$ are the same finite and total tree. \hfill $\Box$

Strict equality allows us to characterize the subset of $\mathcal{IT}$ consisting of finite and total trees: $x$ is a finite and total tree $\iff x == x$.

In Figure 1, we propose an axiomatization of infinite trees with strict equality, which is similar, but not equal, to the one of finite trees with equality given in [10]. The main difference comes from the fact that strict equality is not reflexive: because of $A_3$ and $A_4$, non-finite/non-total trees are not strictly equal to themselves. Due to this property, $\bot$ and the remaining function symbols in $\mathcal{T}_\Sigma$ have a different treatment. We distinguish two cases, depending on whether the signature $\Sigma$ is either finite or infinite. In the case of infinite signatures, the strict equality theory of infinite trees consists of Axioms $A_3 - A_6$ and is denoted by $\mathcal{E}_{inj}$. For finite signatures, the axiomatization of infinite trees also includes
For every \( f/n \in \mathcal{F}_\Sigma \) such that \( f \neq \perp \)
\[
\forall \vec{x} \forall \vec{y} \left( f(\vec{x}) == f(\vec{y}) \rightarrow \vec{x} == \vec{y} \right)
\]

For every \( f/n, g/m \in \mathcal{F}_\Sigma \) such that \( f \neq g \)
\[
\forall \vec{x} \forall \vec{y} \left( \neg f(\vec{x}) == g(\vec{y}) \right)
\]

For every term \( t[x] \) except \( x \) such that \( \overline{y} = \text{Var}(t[x]) \setminus \{x\} \)
\[
\forall x \forall \overline{y} \left( \neg x == t[x] \right)
\]

\( \forall x \neg x == \perp \)

Symmetry
\[
\forall x \forall y \left( x == y \rightarrow y == x \right)
\]

Transitivity
\[
\forall x \forall y \forall z \left( \neg x == y \lor \neg y == z \lor x == z \right)
\]

Domain Closure Axiom or DCA \% only for finite signatures
\[
\forall x \left( \neg x == x \lor \bigvee_{f/n \in \mathcal{F}_\Sigma} \exists \overline{w} x == f(\overline{w}) \right)
\]

Fig. 1. Axiomatization of Infinite Trees with Strict Equality

Axiom \( A_7 \) and is denoted by \( \mathcal{E}_{fin} \). Axiom \( A_7 \) is an adaptation of the Domain Closure Axiom introduced in [12] to the case of strict equality, which prevents the existence of isolated finite and total trees in the algebra. Note that \( A_7 \) does not provide any information about non-finite/non-total trees.

To simplify statements and reasonings, we will frequently use \( \mathcal{E} \) to refer indistinctly to \( \mathcal{E}_{inf} \) and \( \mathcal{E}_{fin} \) for the respective cases of infinite and finite signatures.

We will also abuse of notation \( \mathcal{IT} \) to refer either to the set of infinite trees or the interpretation with \( \mathcal{IT} \) as carrier and symbols in \( \Sigma \) interpreted in the natural way (symbols in \( \mathcal{F}_\Sigma \) as free constructors and == as strict equality).

Three basic questions about \( \mathcal{E} \) arise: Are the axioms of \( \mathcal{E} \) correct for \( \mathcal{IT} \)? Are there enough axioms as to characterize ==? Are there too many? The first and third questions are solved in the next proposition. The second one concerns completeness of \( \mathcal{E} \), and is far from being a trivial question. It will be proved by means of a decision procedure based on some equivalences under \( \mathcal{E} \) used as transformation rules for quantifier elimination.

**Theorem 1** (Correctness and minimality of \( \mathcal{E} \)).

(i) \( \mathcal{IT} \models \mathcal{E} \).

(ii) No strict subset of \( \mathcal{E} \) is a complete theory.

**Proof.** A direct inspection of \( \mathcal{E} \) proves (i). For (ii), it is enough to prove that \( \mathcal{E} \setminus \{A_i\} \) is not complete, for each axiom \( A_i \), taken from \( \mathcal{E} \). This is proved by
giving a model $\mathcal{M}$ of $\mathcal{E} \setminus \{A_1\}$ and a closed formula $\varphi$ that is valid in $\mathcal{M}$ but not in $\mathcal{IT}$ (therefore $\neg \varphi$ is valid in $\mathcal{IT}$). Since $\mathcal{M}$ and $\mathcal{IT}$ are both models of $\mathcal{E} \setminus \{A_1\}$, neither $\varphi$ nor $\neg \varphi$ can be deduced from $\mathcal{E} \setminus \{A_1\}$, which therefore is not complete. Let us examine $\mathcal{E} \setminus \{A_i\}$ for the interesting $i$’s. We assume a constant $a$ and a function symbol $f_i/n$ ($n > 0$, say $n = 1$ for simplicity) in $\mathcal{F}_\Sigma$.

(A_1) We build a model $\mathcal{M}$ of $\mathcal{E} \setminus \{A_1\}$ as follows: The carrier and the interpretation of symbols $\mathcal{M}$ are as in the standard interpretation $\mathcal{IT}$, with the exception that $f_M(\bot)$ is defined to be the tree $f(a)$ (instead of being the tree $f(\bot)$, as in the standard $\mathcal{IT}$). It is not difficult to see that $\mathcal{M}$ is indeed a model of $\mathcal{E} \setminus \{A_1\}$. Now we can take $\varphi = f(\bot) = f(a)$ as the desired formula such that $\mathcal{M} \models \varphi$ and $\mathcal{IT} \models \neg \varphi$.

(A_2) We build a model $\mathcal{M}$ of $\mathcal{E} \setminus \{A_2\}$ as follows: the carrier and the interpretation of function symbols of $\mathcal{F}_\Sigma$ are as in the standard interpretation $\mathcal{IT}$. However, $\equiv$ is interpreted as follows:

$$x \equiv_M y \iff x \text{ and } y \text{ are any finite and total trees}$$

It is not difficult to see that $\mathcal{M}$ is indeed a model of $\mathcal{E} \setminus \{A_2\}$. Now we can take $\varphi = a \equiv f(a)$ as the desired formula such that $\mathcal{M} \models \varphi$ and $\mathcal{IT} \models \neg \varphi$.

(A_3) In this case, the carrier of $\mathcal{M}$ is the set of possibly partial infinite trees built with $\mathcal{F}_\Sigma \cup \{b/0\}$, where $b$ is a new constant. All symbols in $\Sigma$ are interpreted as usual, except that $f_M(b)$ is defined to be the tree $b$ instead of being the tree $f(b)$ (that exists also in the carrier). It can be seen that $\mathcal{M}$ is a model of $\mathcal{E} \setminus \{A_3\}$. Note that $b =^M b$ holds in the carrier. This does not contradict the axiom scheme $A_2$ (because $\forall x b = x$ is not an instance of $A_2$, as $b$ is not in the original $\Sigma$), but serves to show that $\mathcal{M} \models \varphi$ where $\varphi = \exists x x = f(x)$. However $\mathcal{IT} \models \neg \varphi$, since $\neg \varphi$ is equivalent to $\forall x \neg x = f(x)$, which is an instance of $A_3$.

(A_4) We build a model $\mathcal{M}$ of $\mathcal{E} \setminus \{A_4\}$ as follows: As for $A_4$, the carrier and the interpretation of function symbols of $\mathcal{F}_\Sigma$ are as in the standard interpretation $\mathcal{IT}$, and only the interpretation of $\equiv$ is changed with respect to the standard $\mathcal{IT}$:

$$x \equiv_M y \iff x \text{ and } y \text{ are the same finite tree}$$

It is not difficult to see that $\mathcal{M}$ is indeed a model of $\mathcal{E} \setminus \{A_4\}$. Now we can take $\varphi = \bot = \bot$ as the desired formula such that $\mathcal{M} \models \varphi$ but $\mathcal{IT} \models \neg \varphi$.

We end the section with a useful property, which can be seen as a weak version of reflexivity.

**Proposition 1.**

$$\mathcal{E} \models \forall x \ (x = x \iff \exists y \ x = y)$$

**Proof.** One implication is trivial. The reverse implication is proved by symmetry and transitivity. $\square$

Fig. 2. Transformation Rules
4 Transformation Rules

In Figure 2, we summarize the transformation rules that are used in Section 5 for providing a decision method for $E$. Note that some conditions in the rules, like those of rule $R$, are not necessary for correctness. Instead, they serve to discard the application of some rules when there exist more suitable ones. Next, we prove that the transformation rules in Figure 2 are correct.

**Theorem 2.** The transformation rules in Figure 2 are correct in $E$.

**Proof.** See Appendix. $\square$

5 A Decision Method for Strict Equality

In this section, we prove that the theory of strict equality is decidable by providing an algorithm that transforms any initial constraint into an equivalent disjunction of formulas in solved form. This algorithm is based on the well-known technique of quantifier elimination, as the algorithms proposed in [5, 10] for the equality theory. As in the above cited works, we distinguish two cases depending on whether the signature is finite or infinite. In the next subsections, we first provide a decision algorithm for the case of infinite signatures and then adapt that algorithm for finite ones.

5.1 Infinite Signatures

In order to provide a decision algorithm, we first define a solved form for infinite signatures, called basic formula. Then, we show that two basic Boolean operations —conjunction and negation— can be performed on basic formulas. And, finally, we describe the decision algorithm.

**Definition 2.** A basic formula for the variables $\pi$ is either true, false (closed basic formulas) or a constraint $\exists w \phi$ such that

$$c(\pi, w) = \bigwedge_{x_1 \in \pi^1} \neg x_1 == x_1 \land \pi^2 == \overline{t} \land \bigwedge_{w_i \in w} \bigwedge_{j=1}^{n_i} (\neg w_i == s_{ij})^{\gamma_i} \land \overline{w}$$

where $\pi = \pi^1 \cup \pi^2$ and $\pi^1 \cap \pi^2 = \emptyset$,

- $\overline{w} = \text{Var}(\overline{t})$ and $\pi \cap \overline{w} = \emptyset$,

- if $s_{ij}$ is a variable, then $s_{ij} \in \overline{w}$, otherwise $s_{ij}$ is total, $w_i \notin \text{Var}(s_{ij})$ and $\text{Var}(s_{ij}) \cap \pi = \emptyset$ for every $w_i \in \overline{w}$ and $1 \leq j \leq n_i$.

A formula is in basic normal form (or BNF) if it is of the form $Q\overline{y} \phi[\pi \cdot \overline{y}]$ where $\phi$ is a disjunction of basic formulas for $\pi \cdot \overline{y}$. $\square$

**Example 1.** Let $\{a_{10}, g_{11}, f_{22}\} \subset \Sigma$ and $\overline{\pi} = \{x_1, x_2, x_3\} \subset \gamma$. The sentences $\exists \overline{w} (\neg x_1 == x_1 \land x_2 == g(w_1) \land x_3 == g(w_2) \land \neg w_1 == w_2 \land \forall v \neg w_2 == f(a, v))$, $(\neg x_1 == x_1 \land \neg x_2 == x_2 \land \neg x_3 == x_3)$ and $\text{true}$ are basic formulas for $\overline{\pi}$. $\square$
First, we will show that the notion of basic formula is a solved form.

**Theorem 3.** Any basic formula different from false is satisfiable in $\mathcal{E}_{\text{inf}}$.

**Proof.** The constraint $\text{true}$ is trivially satisfiable. Thus, let us consider a basic formula for the variables $\pi$ of the form

$$\exists \pi \left( \bigwedge_{x_1 \in \pi} \neg x_1 == x_1 \land \pi^2 == \top \land \bigwedge_{w_i \in \pi} \bigwedge_{j=1}^{n_i} (\neg w_i == s_{ij})^{\pi \setminus \pi_i} \right).$$

The conjunction $\bigwedge_{x_1 \in \pi} \neg x_1 == x_1$ is trivially satisfiable since the variables $x_1$ do not occur in the rest of the basic formula. Hence, each variable in $\pi_1$ can be assigned to a non-finite/non-total term without restrictions. The conjunction $\pi^2 == \top$ is also satisfiable since it is an idempotent substitution. Therefore, we focus on $\varphi = \bigwedge_{w_i \in \pi} \bigwedge_{j=1}^{n_i} (\neg w_i == s_{ij})^{\pi \setminus \pi_i}$. Being a finite conjunction, the number of function symbols occurring in some negated equation is necessarily finite. Thus, there exists an assignment to the variables $\pi$ consisting of distinct finite and total trees, each one of them starting by a function symbol not occurring in $\varphi$. Hence, the basic formula is satisfiable. $\square$

Then, we describe the transformation of any universally quantified disjunction of negated equations into an equivalent disjunction of basic formulas.

**Proposition 2.** Any universally quantified disjunction of negated equations

$$\forall \pi \left( \neg w_1 == t_1 \lor \neg w_2 == t_2 \lor \ldots \lor \neg w_n == t_n \right) \quad (1)$$

where $w_i \notin \pi$ for each $1 \leq i \leq n$ can be transformed into an equivalent disjunction of basic formulas for the variables $\tilde{\pi} = \text{Var}(t_1, \ldots, t_n) \setminus \pi$.

**Proof.** If $n = 0$, then the proof is trivial. Assuming that $n > 0$, formula (1) is transformed into

$$\forall \pi^1 \left( \neg w_1 == t_1 \right) \lor \exists \pi^1 \left( w_1 == t_1 \land \forall \pi^2 \left[ \neg w_2 == t_2 \lor \ldots \lor \neg w_n == t_n \right] \right)$$

using $S$, where $\pi^1 = \text{Var}(t_1) \cup \pi$ and $\pi^2 = \pi \setminus \pi^1$. The formula $\forall \pi^1 \left( \neg w_1 == t_1 \right)$ can be transformed into a disjunction of basic formulas for $\pi$ by applying the rule $T$ on each variable from $\pi$ and the rules $\text{NFT}_1$, $\text{EI}$ and $\text{R}$ on $w_1$. Using the same transformation, $\varphi$ can be transformed into a disjunction of basic formulas for the variables $\pi \setminus w_1$ which, in conjunction with $w_1 == t_1$, is a disjunction of basic formulas for $\pi$. $\square$

Using the above transformation, we now describe the implementation of the Boolean operations conjunction and negation on basic formulas.

**Proposition 3.** A conjunction of disjunctions of basic formulas for $\pi$ can be transformed into an equivalent disjunction of basic formulas for $\pi$. 
Proof. It suffices to show that a conjunction of two basic formulas for the variables \( \varphi \) can be transformed into an equivalent disjunction of basic formulas for \( \varphi \). The extension to the general case is trivial. Let us consider the following two constraints:

\[
c_1(\varphi, \overline{\varphi}^1) = \bigwedge_{x_1 \in \varphi^1} \neg x_1 == x_1 \land \varphi^{21} == \overline{t}^1 \land \bigwedge_{w^1_j \in \overline{\varphi}^1} \neg w^1_j == s^1_j \land \overline{\varphi}^1
\]

\[
c_2(\varphi, \overline{\varphi}^2) = \bigwedge_{x_1 \in \varphi^2} \neg x_1 == x_1 \land \varphi^{22} == \overline{t}^2 \land \bigwedge_{w^2_j \in \overline{\varphi}^2} \neg w^2_j == s^2_j \land \overline{\varphi}^2
\]

If either \( \varphi^{11} \neq \varphi^{12} \) or \( \overline{t}^1 \) and \( \overline{t}^2 \) do not unify, then

\[
\exists \overline{\varphi}^1 c_1(\varphi, \overline{\varphi}^1) \land \exists \overline{\varphi}^2 c_2(\varphi, \overline{\varphi}^2) \equiv false
\]

(by rules \( \text{NFT}_2 \) and \( \text{C}_1 \) respectively). Otherwise, \( \varphi^{11} = \varphi^{12} \) (thus, \( \varphi^{21} = \varphi^{22} \)), \( \sigma = \text{mgu}(\overline{t}^1, \overline{t}^2) \) and the conjunction \( c_1(\varphi, \overline{\varphi}^1) \land c_2(\varphi, \overline{\varphi}^2) \) is equivalent (by rules \( \text{R, D}_1, \text{EE}_2 \) and \( \text{FT/EE}_1 \)) to

\[
\bigwedge_{x_1 \in \varphi} \neg x_1 == x_1 \land \varphi^2 == \overline{\varphi}^2 \land \bigwedge_{w^1_j \in \overline{\varphi}^1} \neg w^1_j == s^1_j \land \overline{\varphi}^1
\]

where \( \varphi^1 = \varphi^{11} = \varphi^{12}, \varphi^2 = \varphi^{21} = \varphi^{22}, \overline{t} = \text{mgu}(\overline{t}^1, \overline{t}^2) \) and \( \overline{\varphi} = \text{Var}(\overline{t}) \). Then, using \( \text{D}_2, \text{C}_2 \) and \( \text{UE} \), each negated equation \( \neg w^k_j \sigma == s^k_{ij} \land \overline{\varphi}^k \) for \( 1 \leq j \leq n^k \), \( w^k \in \overline{\varphi}^k \) and \( k \in \{1, 2\} \) is transformed into \( true, false \) or an equivalent disjunction of the form

\[
\bigvee \forall \overline{\varphi} \left( \neg w^1 == s^1 \lor \neg w^2 == s^2 \lor \ldots \lor \neg w^m == s^m \right)
\]

(2)

where \( \overline{\varphi} \subseteq \overline{\varphi}, w_i \in \overline{\varphi} \) for each \( 1 \leq i \leq m \). If \( \overline{\varphi} = \emptyset \), then (2) is transformed into a conjunction of basic formulas for \( \overline{\varphi} \) (as proposed in Proposition 2). Then, the whole formula is simplified by distribution. Note that a conjunction of \( \varphi^2 == \overline{t}[w] \land \neg w == w \) is easily reduced to \( false \) by rule \( \text{NFT}_2 \). For the remaining cases, we use rules \( \text{R, EE}_2 \) and \( \text{FT/EE}_1 \) on the variables \( \overline{\varphi} \). After using the rule \( \text{R} \), we may have to simplify the conjunction of negated equations as above. However, this process clearly ends since the depth of universal variables strictly decreases at each iteration. \( \square \)

In the next example, we show the transformation of a conjunction of two basic formulas into an equivalent disjunction of basic formulas for the same variables.
Example 2. Let \( \{a,0, g, f, 2\} \subset \mathcal{F}_\Sigma \) and \( \mathcal{F} = \{x_1, x_2, x_3\} \subset \mathcal{V} \). The conjunction of basic formulas for \( \mathcal{F} \varphi_1 = \exists m^1 c_1(\mathcal{F}, \mathcal{W}^1) \wedge \exists m^2 c_2(\mathcal{F}, \mathcal{W}^2) \) where

\[
\begin{align*}
c_1(\mathcal{F}, \mathcal{W}^1) & = \neg x_1 == x_1 \wedge x_2 == w_1^1 \wedge x_3 == g(w_1^2) \wedge \forall v \neg w_1^1 == f(a, v) \\
c_2(\mathcal{F}, \mathcal{W}^2) & = \neg x_1 == x_1 \wedge \neg x_2 == x_2 \wedge x_3 == f(w_2^1, w_2^2) \wedge \neg w_1^2 == w_2^1
\end{align*}
\]

is unsatisfiable since \( x_2 == w_1^1 \wedge \neg x_2 == x_2 \) is reduced to false by NFT\(_2\). On the contrary, the conjunction \( \varphi_2 = \exists m^1 c_1(\mathcal{F}, \mathcal{W}^1) \wedge \exists m^3 c_3(\mathcal{F}, \mathcal{W}^3) \) where

\[
\begin{align*}
c_3(\mathcal{F}, \mathcal{W}^3) & = \neg x_1 == x_1 \wedge x_2 == f(w_3^1, w_3^2) \wedge x_3 == w_3^1 \wedge \forall v \neg w_3^3 == g(v)
\end{align*}
\]

is transformed in the following way. Since \( \sigma = \text{mgw}(w_1^1 \cdot g(w_1^2), f(w_1^1, w_2^2) \cdot w_3^1) = \{w_1^1 \leftarrow f(g(w_1^1), w_2^2), w_1^3 \leftarrow g(w_2^1)\} \), \( \varphi_2 \) is transformed into

\[
\exists w_1^1 \cdot w_2^2 (\neg x_1 == x_1 \wedge x_2 == f(g(w_1^1), w_2^2) \wedge x_3 == g(w_2^1) \wedge \forall v \neg f(g(w_1^2), w_2^3) == f(a, v) \wedge \forall v \neg w_3^3 == g(v)).
\]

Then, the negated equation \( \forall v \neg f(g(w_1^2), w_2^3) == f(a, v) \) is reduced to true using rules \( D_2 \) and \( C_2 \). Thus, the resulting basic formula is

\[
\exists w_1^3 \cdot w_2^3 (\neg x_1 == x_1 \wedge x_2 == f(g(w_1^1), w_2^3) \wedge x_3 == g(w_2^3) \wedge \forall v \neg w_3^3 == g(v)).
\]

Proposition 4. A negated disjunction of basic formulas for the variables \( \mathcal{F} \) can be transformed into an equivalent disjunction of basic formulas for \( \mathcal{F} \).

Proof. It suffices to show that a negated basic formula for the variables \( \mathcal{F} \) can be transformed into an equivalent disjunction basic formulas for \( \mathcal{F} \). By Proposition 3, the extension to the general case is straightforward.

Let us consider the following negated basic formula for the variables \( \mathcal{F} \):

\[
\neg \exists m \left( \bigwedge_{x_1 \in \mathcal{F}} \neg x_1 == x_1 \wedge \mathcal{F}^2 == \bar{L} \wedge \bigwedge_{w_i \in \mathcal{W}} \bigwedge_{j=1}^{n_1} \neg w_i == s_{ij} \right)
\]

By distribution, the above formula is transformed into

\[
\bigvee_{x_1 \in \mathcal{F}} x_1 == x_1 \vee \neg \exists m \left( \mathcal{F}^2 == \bar{L} \wedge \bigwedge_{w_i \in \mathcal{W}} \bigwedge_{j=1}^{n_1} \neg w_i == s_{ij} \right)
\]

where each \( x_1 == x_1 \) from the first subformula is transformed into a disjunction of basic formulas for \( \mathcal{F} \) by applying the rule \( T \) on each variable from \( \mathcal{F} \backslash x_1 \). Using the rule \( S \), the second subformula is transformed into

\[
\neg \exists m \left( \mathcal{F}^2 == \bar{L} \right) \vee \exists m \left( \mathcal{F}^2 == \bar{L} \wedge \bigwedge_{w_i \in \mathcal{W}} \bigwedge_{j=1}^{n_1} \neg w_i == s_{ij} \right).
\]

By Proposition 2, \( \neg \exists m \left( \mathcal{F}^2 == \bar{L} \right) \) is transformed into a disjunction of basic formulas for \( \mathcal{F}^2 \). Besides, after simplification and double negation elimination, the remaining subformula is transformed into a disjunction of basic formulas for \( \mathcal{F}^2 \) using rules \( R, EE_2, FT \) and \( EE_1 \) on \( w_i == s_{ij} \) for each \( w_i \in \mathcal{W} \) and \( 1 \leq j \leq n_i \). Finally, basic formulas for \( \mathcal{F}^2 \) are transformed into basic formulas for \( \mathcal{F} \) using rules \( T \) and \( EI \) on each variable from \( \mathcal{F}^1 \).  \( \square \)
Example 3. Let \( \{a, f/j_2\} \in \mathcal{F}_\Sigma \) and \( \mathcal{F} = \{x_1, x_2\} \subset \mathcal{V} \). The negated basic formula for the variables \( \mathcal{F} \)

\[
\varphi = \neg \exists w \ ( \neg x_1 == x_1 \land x_2 == f(w, a) \land \forall w \neg w == f(a, v) )
\]
is transformed as follows. First, \( \varphi \) is trivially equivalent to

\[
( x_1 == x_1 ) \lor \neg \exists w \ ( x_2 == f(w, a) \land \forall w \neg w == f(a, v) )
\]

where \( ( x_1 == x_1 ) \) is transformed into the following basic formulas for \( \mathcal{F} \)

\[
\exists w_1 \ ( \neg x_2 == x_2 \land x_1 == w_1 ) \lor \exists w_2 \cdot w_3 \ ( x_1 == w_2 \land x_2 == w_3 )
\]

using \( T, \ EI, R \) and \( FT \). Besides, the remaining subformula is transformed into

\[
\neg \exists w \ ( x_2 == f(w, a) ) \lor \exists w \ ( x_2 == f(w, a) \land \forall w \neg w == f(a, v) )
\]

using the rule \( S \). The constraint \( \neg \exists w \ ( x_2 == f(w, a) ) \) is transformed into

\[
( \neg x_1 == x_1 \land \neg x_2 == x_2 ) \lor
\exists w_4 \ ( \neg x_1 == x_1 \land x_2 == w_4 \land \forall w \neg w_4 == f(v, a) ) \lor
\exists w_5 \ ( \neg x_2 == x_2 \land x_1 == w_5 ) \lor
\exists w_6 \cdot w_7 \ ( x_1 == w_6 \land x_2 == w_7 \land \forall w \neg w_7 == f(v, a) )
\]

using \( T, \ EI, R \) and \( \text{NFT}_1 \). Finally, \( \exists w \ ( x_2 == f(w, a) \land \forall w \neg w == f(a, v) ) \equiv \exists w \ ( x_2 == f(w, a) \land \exists v w == f(a, v) ) \) is transformed into

\[
\exists w_8 \ ( \neg x_1 == x_1 \land x_2 == f(f(a, w_8), a) ) \lor
\exists w_9 \cdot w_{10} \ ( x_1 == w_9 \land x_2 == f(f(a, w_{10}), a) )
\]

using rules \( R, \ EE_2 \) and \( FT \) on \( w \), and \( T \) and \( EI \) on \( x_1 \).

\[
(\text{EE}_4) \ \exists \mathcal{W} \ ( \mathcal{V} == \mathcal{W} \land \bigwedge_{i=1}^{n} (\neg s_i == t_i) \land \mathcal{W} \land \varphi ) \rightarrow \varphi
\]

if \( \mathcal{W} \cap \text{Var}(\varphi) = \emptyset, \mathcal{W} \subseteq \mathcal{W}, s_i \neq t_i, \mathcal{W} \cap \text{Var}(s_i, t_i) \neq \emptyset \) and either

\( s_i \) (resp. \( t_i \)) is not a variable or \( s_i \in \mathcal{W} \) (resp. \( t_i \in \mathcal{W} \)) for each \( 1 \leq i \leq n \)

Fig. 3. Existential Quantification Elimination: Infinite Signatures

Next, we show that the elimination of the innermost block of quantifiers is correct in \( \mathcal{L}_{uf} \) when it is existential. For this purpose, we introduce the transformation rule \( \text{EE}_4 \) (see Figure 3), which allows to eliminate existential variables only occurring in a conjunction of (universally quantified) negated equations.
Given any constraint $\varphi_0$ with free variables $\pi^0$:

**Step 1** Transform $\varphi_0$ into a prenex DNF formula $\varphi_1 = Q_1 \pi^1 \ldots Q_n \pi^n \bigvee_{i=1}^m \psi_i$

**Step 2** For each $1 \leq i \leq m$, transform $\psi_i$ into a disjunction of basic formulas for the variables $\pi = \pi^0, \pi^1, \ldots, \pi^n$ as follows:

(a) Apply rules $B_1$, $B_2$, $\text{NFT}_1$, $\text{NFT}_2$, $\text{FT}$, $D_1$, $D_2$, $C_1$, $C_2$, $O_1$, and $O_2$. When none of the previous rules applies, it remains a disjunction of constraints of the form $\psi'_i = \bigwedge_{j=1}^{n_i} v_j \iff r_j \land \bigwedge_{j=n_i+1}^{n_j} \neg v_j \iff r_j$ where $v_i$ is a variable, $r_j$ is total and $v_j \notin \text{Var}(r_j)$ for each $1 \leq j \leq o_2$.

(b) For each conjunct $\psi'_i$ that results from (a) and each variable $x \in \pi$:
- If $x = v_j$ for some $1 \leq j \leq o_1$, then apply $R$ on $x$.
- If $x \neq v_i$ for every $1 \leq j \leq o_1$ and $x \in \text{Var}(r_i)$ for some $1 \leq k \leq o_1$, then apply $\text{EI}$ and $R$ on $x$.
- Otherwise, apply $T$ on $x$ and goto (a).

The resulting formula $\varphi_2 = Q_1 \pi^1 \ldots Q_n \pi^n \bigvee_{i=1}^{m'} \exists \pi^i a_i(\pi, \pi^i)$ is in BNF

**Step 3** Iteratively eliminate the innermost block of consecutive existential/universal quantifiers $Q_n \pi^n$ in $\varphi_2$:

(i) If $Q_n = \exists$, by Theorem 4 (Theorem 7 for finite signatures) the formula $\varphi_2$ is equivalent to $Q_1 \pi^1 \ldots Q_{n-1} \pi^{n-1} \bigvee_{i=1}^{m'} \exists \pi^i a_i(\pi, \pi^i)$

(ii) If $Q_n = \forall$, then apply (i) using double negation as follows $Q_1 \pi^1 \ldots \forall \pi^n \forall \pi^{m'} \exists \pi^i a_i(\pi, \pi^i)$. Negation on basic formulas is therefore used before and after applying (i).

---

*Proposition 5.* The transformation rule $\text{EE}_4$ is correct in $\mathcal{E}_{nf}$.

*Proof.* We have to prove that

$$\mathcal{E}_{nf} \models [ \exists \pi ( \pi = \pi \land \bigwedge_{i=1}^n (\neg s_i = t_i) \bigvee \forall \pi \land \varphi ) \iff \varphi ].$$  

One implication is trivial. For the reverse one, it suffices to show the existence of a witness for $\exists \pi$. Since $\psi = \bigwedge_{i=1}^n (\neg s_i = t_i) \bigvee \forall \pi$ is a finite conjunction, we can use as witness any ground term such that its root function does not occur in $\psi$. 

The elimination of the innermost block of existential quantifiers is used in the decision algorithm given in Figure 4.

*Theorem 4.* Let $\exists \pi a(\pi \cdot \gamma, \pi \cdot \beta)$ be a basic formula for $\pi \cdot \gamma$ of the form

$$\exists \pi \cdot \beta \left( \bigwedge_{x_1 \in \pi^1} \neg x_1 = x_1 \land \bigwedge_{y_1 \in \pi^1} \neg y_1 = y_1 \land \beta = \beta \iff \beta \land \varphi \land \psi \right)$$
where \( \bar{w} = \text{Var}(\overline{t}) \) and \( \bar{x} = \text{Var}(\overline{\varphi}) \setminus \bar{w} \),
\[- \varphi \] is a finite conjunction of negated equations such that \( \text{Free}(\varphi) \subseteq \bar{w} \),
\[- \psi = \bigwedge_{i=1}^{n} (\neg w_i == s_i)^{\bar{w} \setminus \bar{x}} \text{ and } (w_i \cup \text{Var}(s_i)) \cap \bar{x} \neq \emptyset \text{ for } 1 \leq i \leq n. \]

The formulas \( \exists y [ \exists w (\overline{x} \cdot \overline{y} \cdot \overline{z}) ] \) and \( \exists w a'(\overline{x}, \overline{w}) \) where
\[
a'(\overline{x}, \overline{w}) = \bigwedge_{x \in \overline{y}} \neg x \equiv x_1 \land \overline{x}^2 \equiv \top \land \varphi
\]
are equivalent in \( \mathcal{E}_{inf} \).

**Proof.** It follows from rules EE1, EE2, EE3 and EE4. \( \square \)

**Example 4.** Let \( \{a/0, g/1, f/2\} \subset \mathcal{F}_{\Sigma} \). The formulas
\[
\exists y [ \exists w_1 \cdot w_2 ( x == g(w_1) \land y == f(w_2, a) \land \neg w_1 == a \land \\
\neg w_1 == w_2 \land \forall v \neg w_2 == f(a, v) ) ]
\]
and \( \exists w_1 ( x == g(w_1) \land \neg w_1 == a ) \) are equivalent in \( \mathcal{E}_{inf} \). \( \square \)

The algorithm described in Figure 4 is illustrated in the next example. Roughly speaking, we first transform the input constraint \( \varphi \) into an equivalent formula in basic normal form. Then, we proceed to iteratively eliminate the innermost block of quantifiers \( Q_i \overline{x}^i \). By Theorem 4, the elimination of \( Q_i \overline{x}^i \) is trivial when \( Q_i \) is existential. However, when \( Q_i \) is universal, we have to use double negation to turn \( Q_i \) into existential. This process requires to negate the matrix of the formula and to transform it into an equivalent disjunction of basic formulas for the same variables before and after the elimination of \( Q_i \). In both cases, the length of the block of consecutive quantifiers strictly decreases at each elimination step because no new variable is introduced in the prefix. Hence, since the length of the prefix is finite, the algorithm always terminates and transforms \( \varphi \) into an equivalent disjunction of basic formulas for its free variables.

**Example 5.** Let \( \{a/0, g/1, f/2\} \subset \mathcal{F}_{\Sigma} \) and \( \overline{x} = \{x_1, x_2\} \subset \mathcal{V} \). The constraint
\[
\forall \overline{x} [ ( f(x_1, a) == f(g(x_2), x_2) \land \neg g(x_2) == g(g(x_1)) ) \lor f(x_1, x_2) == f(x_2, x_1) ]
\]
is already in prenex disjunctive normal form, thus **Step 1** is not applicable. In **Step 2**, the formula is first transformed into
\[
\forall \overline{x} [ ( x_1 == g(x_2) \land x_2 == a \land \neg x_2 == g(x_1) ) \lor x_1 == x_2 ]
\]
using \( D_1 \) and \( D_2 \). Next, the formula is transformed into basic normal form
\[
\forall \overline{x} [ ( x_1 == g(a) \land x_2 == a ) \lor \exists w ( x_1 == w \land x_2 == w ) ]
\]
using \( R, C_2 \) and \( EI \). Next, in **Step 3**, we proceed to eliminate \( \forall \overline{x} \) (case (ii)). Using double negation, we obtain
\[
\neg \exists \overline{x} [ \neg ( x_1 == g(a) \land x_2 == a ) \land \neg \exists w ( x_1 == w \land x_2 == w ) ]
\]
that is transformed into

\[ \neg \exists x \left( \neg x_1 = x_1 \land \neg x_2 = x_2 \right) \lor \exists w \left( \neg x_1 = x_1 \land x_2 = w \right) \lor \exists w \left( \neg x_2 = x_2 \land x_1 = w \land \neg w = g(a) \right) \lor \exists w \left( x_1 = w_1 \land x_2 = w_2 \land \neg w_1 = g(a) \land \neg w_1 = w_2 \right) \lor \left( \neg x_2 = x_2 \land x_1 = w \right) \lor \exists w \left( x_1 = g(a) \land x_2 = w \land \neg w = a \land \neg w = g(a) \right) \]

by negation and conjunction of basic formulas. Then, the block of quantifiers \( \exists x \) can be eliminated and we obtain \( \neg [ \text{true} ] \), which is trivially equivalent to \( \text{false} \) after simplifying negation.

As an easy but important consequence of having a decision method, we obtain the completeness of our axiomatization \( E_{inf} \).

**Theorem 5 (Completeness of \( E_{inf} \)).** \( E_{inf} \) is a complete theory.

**Proof.** Consider any closed formula \( \phi \). By using the decision method of Fig. 4 we obtain a formula \( \psi \) in BNF such that \( E_{inf} \models \phi \iff \psi \). Now, \( \psi \) must be also closed (since the transformation rules do not introduce new free variables in a formula), and therefore \( \psi \) is a disjunction made of the atoms \( \text{true} \) or \( \text{false} \) (which are the only closed basic formulas). Hence, \( \psi \) is equivalent to \( \text{true} \) or \( \text{false} \). In the first case, we have \( E_{inf} \models \phi \iff \text{true} \), which implies \( E_{inf} \models \phi \). In the second case, we have \( E_{inf} \models \phi \iff \text{false} \), and then \( E_{inf} \models \neg \phi \). Therefore, \( E_{inf} \) is complete.

---

5.2 Finite Signatures

In the case of finite signatures, the normal form provided in Definition 2 is not solved. This arises from the fact that a finite conjunction of universally quantified negated equations on a variable \( w \) may be unsatisfiable if only finite and total trees can be assigned to \( w \). For example, being \( F_{\Sigma} = \{ a/0, g/1 \} \), the constraint

\[ \exists w \left( x = w \land \neg w = a \land \forall v \neg w = g(v) \right) \]

is unsatisfiable although \( \exists w \left( \neg w = a \land \forall v \neg w = g(v) \right) \) is satisfiable. Roughly speaking, the question is that all the function symbols of the signature can be used in a constraint.

Next, we show that \( E_{fin} \) is a decidable theory. For this purpose, we adapt all the definitions and results in Subsection 5.1 to the case of finite signatures. Besides, we add two new transformation rules \( E \) and \( EE_5 \) (see Figure 5). Rule \( E \), whose correctness directly follows from Axiom \( A_7 \), allows for the elimination of universal quantification whereas \( EE_5 \), which is the adaptation of \( EE_4 \) to the case of finite signatures, makes possible to eliminate the innermost block of existential quantifiers. Next, we show that both rules are correct in \( E_{fin} \).

**Proposition 6.** The transformation rules \( EE_5 \) and \( E \) are correct in \( E_{fin} \).
Existential Quantification Elimination

\[ (EE_5) \quad \exists w ( v == v \land \bigwedge_{i=1}^{n} \neg s_i == t_i \land \varphi ) \rightarrow \varphi \]

if \( \overline{w} \cap \Var(\varphi) = \emptyset, \overline{v} \subseteq \overline{w}, s_i \neq t_i \) and \( \overline{w} \cap \Var(s_i,t_i) = \emptyset \) for \( 1 \leq i \leq n \)

Explosion

\[ (E) \quad \varphi[x] \rightarrow \varphi[x] \land [ \neg x == x \lor \bigvee_{f \in \mathcal{F}} \exists \overline{w} x == f(\overline{w}) ] \]

Fig. 5. Transformation Rules: Finite Signatures

Proof. The correctness of \( E \) is straightforward due to \( A_7 \). Regarding to \( EE_5 \), we have to prove that

\[ \mathcal{E}_{\text{fin}} \models [ \exists \overline{w} ( \overline{v} == \overline{v} \land \bigwedge_{i=1}^{n} \neg s_i == t_i \land \varphi ) \leftrightarrow \varphi ] \]

One implication is trivial. For the reverse one, it suffices to show the existence of a witness for \( \overline{w} \). Assuming that \( m \) is the maximum size of any term occurring in \( \bigwedge_{i=1}^{n} \neg s_i == t_i \), we can use as witness a different ground term of size \( m + 1 \) for each variable in \( \overline{w} \).

The use of \( E \) for eliminating universal quantification is necessary because our notion of solved form for finite signatures is free of universal variables.

Definition 3. A basic formula for the variables \( \overline{x} \) is either true, false (closed basic formulas) or a constraint \( \exists \overline{w} c(\overline{x}, \overline{w}) \) such that

\[ c(\overline{x}, \overline{w}) = \bigwedge_{x_1 \in \overline{x}} \neg x_1 == x_1 \land \overline{x}^2 == \overline{t} \land \bigwedge_{w_i \in \overline{w}} \bigwedge_{j=1}^{n_i} \neg w_i == s_{ij} \]

where \( \overline{x} =\overline{x}^1 \cup \overline{x}^2 \) and \( \overline{x}^1 \cap \overline{x}^2 = \emptyset \),

\( \overline{w} = \Var(\overline{t}) \) and \( \overline{x} \cap \overline{w} = \emptyset \),

- if \( s_{ij} \) is a variable, then \( s_{ij} \neq w_i \), otherwise \( s_{ij} \) is total, \( \Var(s_{ij}) \subseteq \overline{w} \)

and \( w_i \notin \Var(s_{ij}) \) for every \( w_i \in \overline{w} \) and \( 1 \leq j \leq n_i \).

A formula is in basic normal form (or BNF) if it is of the form \( Q\overline{y} \varphi[\overline{x} \cdot \overline{y}] \) where \( \varphi \) is a disjunction of basic formulas for \( \overline{x} \cdot \overline{y} \).

As in the case of infinite signatures, the above notion of basic formula is a solved form.

Theorem 6. Any basic formula different from false is satisfiable in \( \mathcal{E}_{\text{fin}} \).

Proof. Obviously, the constraint true is satisfiable. Thus, let us consider a basic formula for the variables \( \overline{x} \) of the form

\[ \exists \overline{w} ( \bigwedge_{x_1 \in \overline{x}} \neg x_1 == x_1 \land \overline{x}^2 == \overline{t} \land \bigwedge_{w_i \in \overline{w}} \bigwedge_{j=1}^{n_i} \neg w_i == s_{ij} ) \]
As in Theorem 3, $\bigwedge_{x_i \in \varphi_1} \neg x_1 == x_1 \land \varphi_2 == \top$ is trivially satisfiable. Regarding $\varphi = \bigwedge_{w_i \in \varpi} \bigwedge_{j=1}^{n_i} (\neg w_i == s_{ij})^\varpi$, each negated equation eliminates either one possible assignment value to $w_i$ if $s_{ij}$ is ground or an assignment value to $\varpi = \text{Var}(s_{ij})$ for each assignment value to $w_i$ if $s_{ij}$ is not ground. The number of assignment values to each variable is infinite, thus $\varphi$ is necessarily satisfiable. □

Note that the syntactical form provided in Definition 3 is a particular case of the one in Definition 2. The only difference is that universal quantification is not allowed in the case of finite signatures. Further, there exists a very simple transformation using $E$ from formulas as defined in Definition 2 into formulas as defined above.

**Proposition 7.** Any constraint of the form $\varphi = \bigwedge_{w_i \in \varpi} \bigwedge_{j=1}^{n_i} (\neg w_i == s_{ij})^\varpi$ can be transformed into an equivalent disjunction of basic formulas for $\varpi$. □

*Proof.* If $\varphi$ is free of universal quantification, then it is transformed into an equivalent disjunction of basic formulas for the variables $\varpi$ as shown in **Step 2** (Figure 4). Otherwise, there exists some $(-w_i == s_{ij})^\varpi$ such that $\text{Var}(s_{ij}) \not\subseteq \varpi$. In order to eliminate universal quantification, we apply $E$ on $w_i$ and, after distributing the new introduced disjunction, rules $\text{NFT}_1$, $R$, $\text{D}_2$ and $\text{C}_2$. In the resulting formula, the depth of the universal variables that come negated equations of the form $(-w_i == s_{ij})^\varpi$ is strictly smaller than the depth of the universal variables in the original formula. Besides, the negated equations of the form $\forall v \neg w_i == v$ (that is, when universal variables occur at depth 0), can be replaced with $\neg w_i == w_i$ by rule $\text{NFT}_3$. Then, this last negated equation is removed using either $\text{NFT}_2$ or $\text{EE}_3$. Thus, we can eliminate all the universal variables by repeating the above described process. □

Being $\exists \varpi \in c(\varphi, \varpi)$ a formula as described in Definition 2, the conjunction of negated equations in $c(\varphi, \varpi)$ is transformed into a disjunction of basic formulas $\varpi$ as shown in Proposition 7. Then, the whole formula is transformed into an equivalent disjunction of basic formulas for $\varphi$ using $R$, $\text{EE}_2$ and $\text{FT}$. This result allows us to easily adapt Propositions 3 and 4 to the case of finite signatures.

**Example 6.** Let $F_{\Sigma} = \{ a_{10}, g_{j1}, f_{j2} \}$ and $\varphi = \{ x_1, x_2 \} \in \mathcal{V}$. The constraint

$$\exists w \ ( \neg x_1 == x_1 \land x_2 == f(w, a) \land \forall v \neg w == f(a, v) )$$

is transformed into a disjunction of basic formulas for $\varphi$ as follows. First, we transform $\forall v \neg w == f(a, v)$ into a disjunction of basic formulas for $w$ using $E$: $\forall v \neg w == f(a, v) \land [ \neg w == w \lor w == a \lor \exists z \ w == g(z) \lor \exists \pi \ w == f(z_1, z_2) ]$. Then, this last disjunction is removed using either $\text{NFT}_2$ or $\text{EE}_3$. Thus, we can eliminate all the universal variables by repeating the above described process. □

$$\exists \pi ( \ w == f(z_1, z_2) \land \forall v \neg w == f(a, v) ) \tag{3}$$
The first three subformulas are already basic formulas for $w$. Regarding the last one, it is transformed using rules $R$ and $D_2$ as follows

$$
\exists z \left( w == f(z_1, z_2) \land \neg z_1 == a \lor \forall v \neg z_2 == v \right)
$$

$$
\equiv \exists z \left( w == f(z_1, z_2) \land \neg z_1 == a \right) \lor \exists z \left( w == f(z_1, z_2) \land \forall v \neg z_2 == v \right) (4)
$$

where the second subformula is equivalent to $false$ by rules $NFT_3$ and $NFT_2$. Thus, $\forall v \neg w == f(a, v)$ has been transformed into the disjunction of basic formulas for $w$ in (3, 4). Finally, the conjunction of the above disjunction and $\neg x_1 == x_1 \land x_2 == f(w, a)$ is transformed into

$$
\exists z \left( w == f(z_1, z_2) \land \neg x_1 == a \right) \lor \exists z \left( w == f(z_1, z_2) \land \forall v \neg z_2 == v \right)
$$

using rules $R$, $EE$ and $NFT_2$. $\square$

Next, in order to be able to apply the algorithm in Figure 4 to the case of finite signatures, we adapt the result in Theorem 4.

**Theorem 7.** Let $\exists \overline{w} (\overline{a} \cdot \overline{y}, \overline{w} \cdot \overline{z})$ be a basic formula for $\overline{a} \cdot \overline{y}$ of the form

$$
\exists \overline{w} \cdot \overline{z} \left( \bigwedge_{x_i \in \overline{x}} \neg x_i == x_i \land \bigwedge_{y_i \in \overline{y}} \neg y_i == y_i \land \overline{x}^2 == \overline{x} \land \overline{y}^2 == \overline{y} \land \varphi \land \psi \right)
$$

where $- \overline{w} = \text{Var} (\overline{t})$ and $\overline{z} = \text{Var} (\overline{y}) \setminus \overline{w}$,

- $\varphi$ is a finite conjunction of negated equations such that $\text{Var} (\varphi) \subseteq \overline{w}$,
- $\psi = \bigwedge_{i=1}^n \neg v_i == s_i$ and $(v_i \cup \text{Var} (s_i)) \cap \overline{z} \neq \emptyset$ for each $1 \leq i \leq n$.

The formulas $\exists \overline{y} \left[ \exists \overline{w} (\overline{a} \cdot \overline{y}, \overline{w} \cdot \overline{z}) \right]$ and $\exists \overline{w} a' (\overline{x}, \overline{w})$ where

$$
a' (\overline{x}, \overline{w}) = \bigwedge_{x_i \in \overline{x}} \neg x_i == x_i \land \overline{x}^2 == \overline{x} \land \varphi
$$

are equivalent in $E_{fin}$.

**Proof.** It follows from rules $EE_1$, $EE_2$, $EE_3$ and $EE_5$. $\square$

Finally, and similarly to the case of infinite signatures (Th. 5), we obtain:

**Theorem 8 (Completeness of $E_{fin}$).** $E_{fin}$ is a complete theory. $\square$

### 6 Conclusions and Future Work

We have axiomatized the theory of infinite trees with strict equality, denoted by either $E_{inf}$ (infinite signatures) or $E_{fin}$ (finite signatures). Besides, we have provided a decision algorithm, which proves that the theory is complete. Our algorithm follows the proposal in [5] for the equality theory of finite trees. Further, it is easy to see that the problem of deciding first-order equality constraints of finite trees can be reduced to the decision problem of the theory of infinite trees.
with strict equality: it suffices to restrict the value of every variable $x$ in any formula to be a finite and total tree by assertions of the form $x == x$. Thus, it follows from the results in [6, 13] that the decision problem of the theory of infinite trees with strict equality is non-elementary (as lower bound).

Although direct applications of our results have been left out of the focus of the paper, we foresee some potential uses that will be subject of future work: Herbrand constraint solvers present in existing functional-logic languages, essentially corresponding to existential constraints, could be enhanced to deal with more general formulas. Constructive failure [9, 8], the natural counterpart of constructive negation in the functional logic field, could also take profit of our methods, specially for the case of programs with extra variables, not considered in the mentioned papers. For these envisaged continuations of our work it could be convenient to extend the theory and methods of this paper by adding two additional predicate symbols: strict disequality (a computable approximation of negation of strict equality) and true equality.

References

Appendix

In order to prove Theorem 2, we first provide the following auxiliary results.

Proposition 8. Replacement (R) is correct in $\mathcal{E}$.

Proof. We have to prove that

$$\mathcal{E} \models ( ( x \equiv t \land \varphi[x] ) \iff ( x \equiv t \land \varphi[x \leftarrow t] ) )^\forall.$$

The proof is made by structural induction on $\varphi$.

The base case, that is $\varphi = r = s[x]$, is proved by induction on the size $n$ of $s[x]$. In the base case $n = 0$, we have that $s[x] = x$ and

$$\mathcal{E} \models ( ( x \equiv t \land r = x ) \iff ( x \equiv t \land r = t ) )^\forall$$

directly follows from transitivity. Assuming as induction hypothesis that

$$\mathcal{E} \models ( ( x \equiv t \land r = s[x] ) \iff ( x \equiv t \land r = s[x \leftarrow t] ) )^\forall \quad (5)$$

holds for any term $s[x]$ of size equal to or smaller than $n$, we have to prove that (5) holds for any term $s[x]$ of size $n + 1$. By Proposition 1, we know that $x \equiv t \land r = s[x] \equiv x \equiv t \land r = s[x] \land s[x] = s[x]$. Besides, since $s[x] = f(\overline{t})$ for some function $f \in F_\Sigma$ and some tuple of terms $\overline{t}$, we have that $x \equiv t \land r = s[x] \land s[x] = s[x] \equiv x \equiv t \land r = s[x] \land \overline{t} = \overline{t}$ by Axiom $\mathbf{A}_1$, where the size of each $u \in \overline{t}$ is equal to or smaller than $n$. By the induction hypothesis, $x \equiv t \land r = s[x] \land \overline{t} = \overline{t} \equiv x \equiv t \land r = s[x] \land \overline{t} = \overline{t}[x \leftarrow t]$. Thus, also by Axiom $\mathbf{A}_1$, we have that $x \equiv t \land r = s[x] \land \overline{t} = \overline{t} \equiv x \equiv t \land r = s[x] \land \overline{t} = \overline{t}[x \leftarrow t]$.

Finally, by transitivity, we know that $x \equiv t \land r = s[x] \land s[x] = s[x \leftarrow t] \equiv x \equiv t \land r = s[x \leftarrow t]$ and, hence, (5) holds for any term $s[x]$ of size $n + 1$.

For the inductive case, we just prove the case for connectives $\neg, \land$ and quantifier $\exists$, since the proof for connectives $\lor, \to, \leftrightarrow$ and quantifier $\forall$ directly follows from it.

If $\varphi = \neg \psi$, then we have to prove that

$$\mathcal{E} \models ( ( x \equiv t \land \neg \psi[x] ) \iff ( x \equiv t \land \neg \psi[x \leftarrow t] ) )^\forall$$

assuming that $\mathcal{E} \models ( ( x \equiv t \land \psi[x] ) \iff ( x \equiv t \land \psi[x \leftarrow t] ) )^\forall$. For any solution $\sigma$ of $x \equiv t$, if $\sigma$ is a solution of $\neg \psi[x]$, then it cannot be a solution of $\psi[x]$. Hence, by induction hypothesis, $\sigma$ is not a solution of $\psi[x \leftarrow t]$ and, therefore, $\sigma$ is a solution of $\neg \psi[x \leftarrow t]$.

If $\varphi = \psi_1 \land \psi_2$, then we have to prove that

$$\mathcal{E} \models ( ( x \equiv t \land \psi_1[x] \land \psi_2[x] ) \iff ( x \equiv t \land \psi_1[x \leftarrow t] \land \psi_2[x \leftarrow t] ) )^\forall$$

assuming that $\mathcal{E} \models ( ( x \equiv t \land \psi_1[x] ) \iff ( x \equiv t \land \psi_1[x \leftarrow t] ) )^\forall$ and $\mathcal{E} \models ( ( x \equiv t \land \psi_2[x] ) \iff ( x \equiv t \land \psi_2[x \leftarrow t] ) )^\forall$. For any solution $\sigma$ of $x \equiv t \land \psi_1[x] \land \psi_2[x]$, $\sigma$ is also solution of $x \equiv t \land \psi_1[x]$ and $x \equiv t \land \psi_2[x]$.
Hence, by induction hypothesis, $\sigma$ is solution of both $x == t \land \psi_1[x \leftarrow t]$ and $x == t \land \psi_2[x \leftarrow t]$ and, therefore, the substitution $\sigma$ is also a solution of $x == t \land \psi_1[x \leftarrow t] \land \psi_2[x \leftarrow t]$.

Finally, if $\varphi = \exists w \psi$, then we have to prove that

$$\mathcal{E} \models [ [ x == t \land \exists w \psi[x] ] \leftrightarrow ( x == t \land \exists w \psi[x \leftarrow t] ) ]^\gamma$$

assuming that $\mathcal{E} \models [ [ x == t \land \psi[x] ] \leftrightarrow ( x == t \land \psi[x \leftarrow t] ) ]^\gamma$. In this case, the proof directly follows from the induction hypothesis since any solution of $x == t \land \psi[x]$ (resp. $x == t \land \psi[x \leftarrow t]$) is also solution of $x == t \land \exists w \psi[x]$ (resp. $x == t \land \exists w \psi[x \leftarrow t]$).

\begin{proof}
\end{proof}

**Proposition 9.** The transformation rules Bottom $(B_1, B_2)$, Non-finite trees $(NFT_1, NFT_2, NFT_3)$, Finite trees (FT), Decomposition $(D_1, D_2)$, Clash $(C_1, C_2)$, Occur-check $(O_1, O_2)$ and Tautology $(T)$ are correct in $\mathcal{E}$.

\begin{proof}
$T$ is trivially correct. The correctness of $D_1$ and $D_2$ is straightforward due to $A_1, C_1$ and $C_2$ are correct due to $A_2$. The correctness of $O_1$ and $O_2$ is straightforward due to $A_3, B_1$ and $B_2$ are correct due to $A_4, NFT_1, NFT_2, NFT_3$ and $FT$ are proved to be correct using symmetry, transitivity, $D_1$ and Proposition 1.
\end{proof}

**Proposition 10.** Existential elimination $(EE_1, EE_2, EE_3)$, Existential introduction $(EI)$ and Universal elimination $(UE)$ are correct in $\mathcal{E}$.

\begin{proof}
Regarding $EE_1$, we have to prove that

$$\mathcal{E} \models [ [ \exists w ( w == w \land \varphi ) \leftrightarrow \varphi ] ]^\gamma.$$

One implication is trivial. For the reverse one, it suffices to show the existence of a witness. We know that there exists at least one constant function symbol $a/j_0 \in \mathcal{F}_2$. Thus, the term $a$ is a witness. The proof for $EE_3$ is almost identical. In this case, we can use $\bot$ as witness.

With respect to $EE_2$, we have to prove that

$$\mathcal{E} \models [ [ \exists w ( w == t \land \varphi ) \leftrightarrow ( \tau == \tau \land \varphi ) ] ]^\gamma.$$

The first implication is proved by Proposition 1 and $D_1$. The reverse implication follows from the existence of a witness (the term $t$ itself).

The correctness of $EI$ is straightforward due to rules $R$, $EE_2$ and $EE_1$.

$UE$ is correct since it results from rules $R$ and $EE_2$ via negation.
\end{proof}

**Proposition 11.** The transformation rule Split $(S)$ is correct in $\mathcal{E}$.

\begin{proof}
We have to prove that

$$\mathcal{E} \models [ [ \neg \exists \overline{w} \exists \overline{z} ( x == t[\overline{w}] \land \varphi[\overline{w}, \overline{z}] ) \leftrightarrow \neg \exists \overline{w} ( x == t[\overline{w}] ) \lor \exists \overline{w} ( x == t[\overline{w}] \land \neg \exists \overline{z} \varphi[\overline{w}, \overline{z}] ) ] ]^\gamma.$$

(6)
For this purpose, we start from the formula
\[ \neg \exists w \exists z (x == t[w] \land \varphi[w \cdot z]) \land (\neg \exists v x == t[v] \lor \exists v x == t[v]) \]
which is trivially equivalent to \( \neg \exists w \exists z (x == t[w] \land \varphi[w \cdot z]) \). By distribution, the above formula is transformed into a disjunction of two conjuncts where the first one
\[ \neg \exists w \exists z (x == t[w] \land \varphi[w \cdot z]) \land \neg \exists w x == t[w] \]
is equivalent to \( \neg \exists w x == t[w] \) (that is, the first conjunct in the right-hand subformula of (6)). From the second conjunct
\[ \neg \exists w \exists z (x == t[w] \land \varphi[w \cdot z]) \land \exists v x == t[v] \]
and using the transformation rule \( \mathbf{R} \), we obtain the formula
\[ \exists v (\neg \exists w \exists z (t[w] == t[w] \land \varphi[w \cdot z]) \land x == t[v]) \]
By simplification, this formula is transformed into
\[ \exists v (x == t[v] \land \forall w \forall z (\neg v == w \lor \neg \varphi[w \cdot z])) \]
which is equivalent to
\[ \exists v (x == t[v] \land (\neg v == v \lor \forall z \neg \varphi[v \cdot z])) \]
using the rule \( \mathbf{UE} \). By distribution, we obtain a disjunction of two formulas
\[ \exists v (x == t[v] \land \neg v == v ) \lor \exists v (x == t[v] \land \forall z \neg \varphi[v \cdot z]) \]
where \( \exists v (x == t[v] \land \neg v == v ) \) is equivalent to \( \text{false} \) by the rule \( \textbf{NFT}_2 \) and \( \exists v (x == t[v] \land \forall z \neg \varphi[v \cdot z]) \) is equivalent to the second conjunct in the right-hand subformula of (6). Thus, formula (6) holds. \( \Box \)

**Theorem 2.** The transformation rules in Figure 2 are correct in \( \mathcal{E} \).

**Proof.** It directly follows from Propositions 8, 9, 10 and 11. \( \Box \)
